Asymptotic formulas for steady state voltage potentials in the presence of thin inhomogeneities. The complex case

Elena Beretta and Elisa Francini

Dedicated to Giovanni Alessandrini on the occasion of his 60th birthday

ABSTRACT. We consider a conducting body with complex valued admittivity containing a finite number of well separated thin inclusions. We derive an asymptotic formula for the boundary values of the potential in terms of the width of the inclusions.

Keywords: Thin inhomogeneities, complex coefficients. MS Classification 2010: 35J25.

1. Introduction

Let $\Omega \subset \mathbb{R}^2$ be a smooth bounded domain representing the region occupied by a conducting body and consider, at a fixed frequency ω , the complex valued admittivity background

$$\gamma_0 = \sigma_0 + i\omega\varepsilon_0$$
 in Ω ,

where σ_0 and ε_0 are real valued functions representing the electrical conductivity and permittivity, respectively.

Let $\Sigma_j \subset \subset \Omega$, for j = 1, ..., N be a collection of simple, regular curves and consider, for ϵ sufficiently small, a neighborhood of Σ_j given by

$$D^j_{\epsilon} = \{ x \in \Omega : dist(x, \Sigma_j) < \epsilon \},\$$

representing a thin inhomogeneity of admittivity

$$\gamma_j = \sigma_j + i\omega\varepsilon_j.$$

Let $\psi \in H^{1/2}(\partial \Omega)$ represents a complex valued boundary current and let

 u_0 be the background potential which satisfies

$$\begin{cases} \operatorname{div}\left(\gamma_{0}\nabla u_{0}\right)=0 & \operatorname{in} & \Omega\\ \gamma_{0}\frac{\partial u_{0}}{\partial \nu}=\psi & \operatorname{on} & \partial\Omega, \end{cases}$$

where ν is the unit outer normal to $\partial\Omega$.

Let

$$\gamma_{\epsilon} = \gamma_0 + \sum_{j=1}^{N} (\gamma_j - \gamma_0) \chi_{D_{\epsilon}^j}$$

and consider the perturbed complex-valued potential u_{ϵ} solution to

$$\begin{cases} \operatorname{div}\left(\gamma_{\epsilon}\nabla u_{\epsilon}\right) = 0 \quad \text{in} \quad \Omega\\ \gamma_{\epsilon}\frac{\partial u_{\epsilon}}{\partial \nu} = \psi \quad \text{on} \quad \partial\Omega \end{cases}$$

The main goal of the paper is to obtain an asymptotic expansion for the boundary values $(u_{\epsilon} - u_0)|_{\partial\Omega}$ as $\epsilon \to 0$.

The formula we derive is analogue to the one obtained in [3] in the case of constant real valued conductivities σ_0 and σ_1 ($\omega = 0$).

More precisely, we show that for $y \in \partial \Omega$ and $\epsilon \to 0$,

$$(u_{\epsilon} - u_0)(y) = \epsilon v(y) + o(\epsilon).$$

where

$$v(y) = \sum_{j=1}^{N} 2 \int_{\Sigma_j} (\gamma_0 - \gamma_j)(x) \mathbb{M}^j(x) \nabla u_0(x) \nabla_x N(x, y) \, d\sigma_x.$$

Here N(x, y) is the Neumann function corresponding to the operator div $(\gamma_0 \nabla \cdot)$ and \mathbb{M}^j is a two by two matrix with complex valued entries.

It is well known that this type of expansion can be used in order to solve the inverse problem of detecting the curves Σ_j , $j = 1, \ldots, N$ from boundary measurements. In fact, in [1] the authors show that for the conductivity equation, it is possible to detect finitely many segments from knowledge on the boundary of the first order term v appearing in the expansion. Moreover they show the continuous dependence of the segments from the boundary measurement v is Lipschitz stable. A similar result has been obtained in the case of the system of linearized elasticity, for the case N = 1, in [2].

2. Main assumptions and results

For j = 1, ..., N, let Σ_j be a simple, regular $C^{2,\alpha}$ curve with $\alpha \in (0,1)$ and assume there exists a contant K > 1 such that, in a neighborhood of radius

 K^{-1} of each point in Σ_i , the curve is the graph of a $C^{2,\alpha}$ function and

$$\begin{aligned} \|\Sigma_j\|_{C^{2,\alpha}} &\leq K, \quad dist(\Sigma_j, \partial\Omega) \geq K^{-1}, \\ K^{-1} &\leq \mathcal{L}(\Sigma_j) \leq K, \quad dist(\Sigma_j, \Sigma_k) \geq K^{-1} \text{ if } j \neq k, \end{aligned}$$
(1)

where \mathcal{L} denotes the length.

On each curve Σ_j we fix an continuous orthonormal system $(n_j(x), t_j(x))$ such that $n_j(x)$ is a normal direction to Σ_j at its point x and $\tau_j(x)$ is a tangent direction.

Assume $\gamma_0, \gamma_j : \Omega \to \mathbb{C}$ such that $\gamma_0 \in C^{1,\alpha}(\Omega), \gamma_j \in C^{\alpha}(\Omega)$ with

$$\|\gamma_0\|_{C^{1,\alpha}(\Omega)}, \|\gamma_j\|_{C^{\alpha}(\Omega)} \le K,\tag{2}$$

and, furthermore, assume there exists $c_0 > 0$ such that

$$\sigma_j \ge c_0, \text{ for } j = 0, 1, \dots, N.$$
 (3)

Consider finally a complex valued flux $\psi \in H^{-1/2}(\partial \Omega)$ satisfying the compatibility condition

$$\int_{\partial\Omega} \psi = 0. \tag{4}$$

Then, under the above assumptions, there exist unique weak solutions u_0 and u_{ϵ} in $H^1(\Omega)$ to

$$\begin{cases} \operatorname{div}\left(\gamma_{0}\nabla u_{0}\right) = 0 & \operatorname{in} & \Omega, \\ \gamma_{0}\frac{\partial u_{0}}{\partial\nu} = \psi & \operatorname{on} & \partial\Omega, \\ \int_{\partial\Omega} u_{0} = 0, \end{cases}$$
(5)

and

$$\begin{cases} \operatorname{div}\left(\gamma_{\epsilon}\nabla u_{\epsilon}\right) = 0 & \text{in} \quad \Omega, \\ \gamma_{\epsilon}\frac{\partial u_{\epsilon}}{\partial\nu} = \psi & \text{on} \quad \partial\Omega, \\ \int_{\partial\Omega} u_{\epsilon} = 0. \end{cases}$$
(6)

We also introduce the Neumann function N solution to

$$\begin{cases} \operatorname{div}\left(\gamma_{0}\nabla N(\cdot,y)\right) = \delta_{y} & \text{in} \quad \Omega, \\ \gamma_{0}\frac{\partial N(\cdot,y)}{\partial\nu} = \frac{1}{\mathcal{L}(\partial\Omega)} & \text{on} \quad \partial\Omega, \\ \int_{\partial\Omega} N(\cdot,y) = 0, \end{cases}$$
(7)

It is well known that under assumptions (2) and (3) there exists a unique solution to (7) (see [5]).

We are now ready to state our main result.

THEOREM 2.1. Let $\Omega \subset \mathbb{R}^2$ be bounded smooth domain and $\{\Sigma\}_{j=1}^N \subset \Omega$ a set of curves satisfying (1), let γ_0 and γ_j (for $j = 1, \ldots, N$) be admittivities satisfying (2) and (3) and let u_0 and u_{ϵ} be solutions to (5) and (6), respectively. Then, for $y \in \partial \Omega$ and $\epsilon \to 0$,

$$(u_{\epsilon} - u_0)(y) = 2\epsilon \sum_{j=1}^N \int_{\Sigma_j} (\gamma_0(x) - \gamma_j(x)) \mathbb{M}^j(x) \nabla u_0(x) \cdot \nabla N(x, y) \, d\sigma_x + o(\epsilon),$$

where

$$\mathbb{M}^{j}(x) = \frac{\gamma_{0}(x)}{\gamma_{j}(x)} n_{j}(x) \otimes n_{j}(x) + \tau_{j}(x) \otimes \tau_{j}(x).$$

3. Proof of Theorem 2.1

We will perform the proof in the case N = 1. Since the curves are well separated one from each other, the same argument will work for the case of multiple inclusions.

A complex valued equation as

$$\operatorname{div}\left(\gamma\nabla u\right) = 0$$

can be interpreted as a two by two system for real valued functions. In fact, denoting by

$$u^1 = \Re u \text{ and } u^2 = \Im u,$$

we have that the function $u = (u^1, u^2) : \Omega \to \mathbb{R}^2$ satisfies the system

1

$$\frac{\partial}{\partial x_k} \left(a_{ij}^{hk} \frac{\partial u^j}{\partial x_k} \right) = 0 \text{ for } i = 1, 2$$

where, for i, j, h, k = 1, 2,

$$a_{ij}^{hk} = \delta_{hk} \delta_{ij} \Re \gamma - \delta_{hk} (\delta_{i1} \delta_{j2} - \delta_{i2} \delta_{j1}) \Im \gamma.$$

If

$$\Re \gamma \ge c_0 > 0,$$

then

$$a_{ij}^{hk}\xi_h^i\xi_k^j \ge c_0|\xi|^2$$

which corresponds to strong ellipticity. For this reason we can apply to our equations the results that hold for strongly elliptic systems.

We first establish some key energy estimates.

LEMMA 3.1. There exists a constant $C = C(K, c_o, \Omega)$ such that

$$||u_{\epsilon} - u_0||_{H^1(\Omega)} \le C |D_{\epsilon}^1|^{1/2} ||\psi||_{H^{-1/2}(\partial\Omega)}.$$

Proof. Since u_0 and u_{ϵ} are solutions to (5) and (6), then $w_{\epsilon} = u_{\epsilon} - u_0$ is weak solution to

$$\begin{cases} \operatorname{div}\left(\gamma_{\epsilon}\nabla w_{\epsilon}\right) &= \operatorname{div}\left((\gamma_{0}-\gamma_{1})\chi_{D_{\epsilon}^{1}}\nabla u_{0}\right) \text{ in }\Omega, \\ \gamma_{\epsilon}\frac{\partial w_{\epsilon}}{\partial \nu} &= 0 \text{ on }\partial\Omega, \\ \int_{\partial\Omega} u_{\epsilon} &= 0. \end{cases}$$

Hence, for every $\phi \in H^1(\Omega)$,

$$\int_{\Omega} \gamma_{\epsilon} \nabla w_{\epsilon} \cdot \nabla \phi = \int_{\Omega} (\gamma_0 - \gamma_1) \chi_{D_{\epsilon}^1} \nabla u_0 \cdot \nabla \phi.$$
(8)

By choosing $\phi = \overline{w}_{\epsilon} \in H^1(\Omega)$, we get

$$\int_{\Omega} \gamma_{\epsilon} |\nabla w_{\epsilon}|^2 = \int_{\Omega} (\gamma_0 - \gamma_1) \chi_{D^1_{\epsilon}} \nabla u_0 \cdot \nabla \overline{w}_{\epsilon}.$$

Now, by (3), we have

$$\|\nabla w_{\epsilon}\|_{L^{2}(\Omega)} \leq C |D_{\epsilon}^{1}|^{1/2} \|\gamma_{0} - \gamma_{1}\|_{L^{\infty}(\Omega)} \sup_{D_{\epsilon}^{1}} |\nabla u_{0}|.$$

By interior regularity results (see [4, Theorem 2.1, Chapter 2]),

$$\sup_{D_{\epsilon}^{1}} |\nabla u_{0}| \leq C \|\psi\|_{H^{-1/2}(\partial\Omega)},$$

so that

$$\|\nabla w_{\epsilon}\|_{L^{2}(\Omega)} \leq C |D_{\epsilon}^{1}|^{1/2} \|\psi\|_{H^{-1/2}(\partial\Omega)}$$

where $C = C(K, c_0)$. Finally, since

$$\int_{\partial\Omega} w_{\epsilon} = 0,$$

by Poincaré inequality we have

$$\|w_{\epsilon}\|_{L^{2}(\Omega)} \leq C \|\nabla w_{\epsilon}\|_{L^{2}(\Omega)}$$

with $C = C(\Omega)$ and we obtain

$$||u_{\epsilon} - u_0||_{H^1(\Omega)} \le |D_{\epsilon}^1|^{1/2} ||\psi||_{H^{1/2}(\partial\Omega)},$$

which ends the proof.

We will also make use of some key regularity results for elliptic systems with discontinuous coefficients due to [6] (that extend the one established in [7] for

scalar elliptic equations). We state here a simplified version of Proposition 5.1 of [6].

Let c and M be two positive constants with M > 2K and denote by $Q_{c,M}$ the set of points $x \in \Omega$ such that $dist(x, \partial \Omega) > M^{-1}$ and such that there is a square of size c centered at x that intersects $\partial D_{\epsilon}^{1}$ in at most two cartesian curves whose $C^{1,\alpha}$ norms are bounded by M, i.e. there exists a coordinate system at xsuch that $\partial D_{\epsilon}^{1} \cap [-c,c]^{2}$ consists in graphs of at most two functions $h_{-} < h_{+}$ with $\|h_{\pm}\|_{C^{1,\alpha}} \leq M$. Let us denote by $\Omega_{M} = \{x \in \Omega : dist(x, \partial \Omega) > \frac{1}{2M}\}$.

LEMMA 3.2. Let $\beta \in (0, 1/4)$ and M > 2K. there exists a constant C depending on α , K, c_0 and M such that if $\epsilon \in (0, \frac{1}{3K})$, $0 < c < \frac{1}{6K}$ and $u_{\epsilon} \in H^1(\Omega)$ is a solution of

$$\operatorname{div}\left(\gamma_{\epsilon}\nabla u\right) = 0 \ in \ \Omega,$$

then

$$\|u_{\epsilon}\|_{C^{1,\beta}(Q_{c,M}\cap\overline{D}_{\epsilon}^{1})} \leq \frac{C}{c^{1+\beta}} \|u_{\epsilon}\|_{L^{2}(\Omega)}$$

$$\tag{9}$$

and

$$\|u_{\epsilon}\|_{C^{1,\beta}(Q_{c,M}\setminus D^{1}_{\epsilon})} \leq \frac{C}{c^{1+\beta}} \|u_{\epsilon}\|_{L^{2}(\Omega)}.$$
(10)

LEMMA 3.3. There exists $\eta > 0$ such that, if $u \in H^1(\Omega)$ is a solution to the complex valued equation

$$\operatorname{div}\left(\gamma\nabla u\right) = f \ in \ \Omega,$$

where $\gamma: \Omega \to \mathbb{C}, \ \gamma \in L^{\infty}(\Omega)$ such that

$$\Re \gamma \ge c_0 > 0$$

and $f \in H^{-1,2+\eta}(\Omega)$, then $u \in H^{1,2+\eta}_{loc}(\Omega)$ and, given B_{ρ} and $B_{2\rho}$ concentric disks contained in Ω ,

$$\|\nabla u\|_{L^{2+\eta}(B_{\rho})} \le C\left(\|f\|_{H^{-1,2+\eta}(B_{2\rho})} + \rho^{\frac{2}{2+\eta}-1} \|\nabla u\|_{L^{2}(B_{2\rho})}\right).$$

For the proof see [4, Chapter 2, Section 10].

Proof of Theorem 2.1. Take $y \in \partial \Omega$. Then, by the definition of the Neumann function, it is easy to see that

$$(u_{\epsilon} - u_0)(y) = \int_{D_{\epsilon}^1} (\gamma_0 - \gamma_1) \nabla u_{\epsilon} \cdot \nabla N(\cdot, y).$$

We prove the theorem in the more interesting and complicated case when Σ_1 is an open curve. In fact, in this case, ∂D_{ϵ}^1 has derivatives (near the endpoints of Σ_1) that degenerate as ϵ tends to zero. This implies that the regularity estimates of Lemma 3.2 cannot be applied near the endpoints of Σ_1 .

Let P_1 and Q_1 be the endpoints of Σ_1 , let $\theta \in (0, 1)$ to be chosen later, and define

$$D_{\epsilon}^{1,\theta} = \left\{ x + \mu n(x) : x \in \Sigma_1, \, dist(x, P_1 \cup Q_1) > \epsilon^{\theta}, \, \mu \in (\epsilon, \epsilon) \right\}.$$

It is easy to see that there exists a constant M > 2K and depending only on K, such that 1 0

$$D^{1,\theta}_{\epsilon} \subset Q_{\frac{\epsilon^{\beta}}{4},M} \cap D^{1}_{\epsilon}.$$

An application of Lemma 3.2 thus gives

$$\|\nabla u_{\epsilon}\|_{C^{\beta}(\overline{D_{\epsilon}^{1,\theta}})} \le C\epsilon^{-\theta(1+\beta)} \|u_{\epsilon}\|_{L^{2}(\Omega)} \le C\epsilon^{-\theta(1+\beta)} \|\psi\|_{H^{-1/2}(\partial\Omega)}$$
(11)

where C does not depend on ϵ .

Then,

$$\begin{split} \int_{D_{\epsilon}^{1}} (\gamma_{0} - \gamma_{1})(x) \nabla u_{\epsilon}(x) \cdot \nabla N(x, y) \, dx \\ &= \int_{D_{\epsilon}^{1, \theta}} (\gamma_{0} - \gamma_{1})(x) \nabla u_{\epsilon}(x) \cdot \nabla N(x, y) \, dx \\ &+ \int_{D_{\epsilon}^{1} \setminus D_{\epsilon}^{1, \theta}} (\gamma_{0} - \gamma_{1})(x) \nabla u_{\epsilon}(x) \cdot \nabla N(x, y) \, dx := I_{1} + I_{2}. \end{split}$$

Let us estimate I_2 first.

$$|I_2| \leq \left| \int_{D_{\epsilon}^1 \setminus D_{\epsilon}^{1,\theta}} (\gamma_0 - \gamma_1) \nabla (u_{\epsilon} - u_0) \cdot \nabla N(\cdot, y) \right| \\ + \left| \int_{D_{\epsilon}^1 \setminus D_{\epsilon}^{1,\theta}} (\gamma_0 - \gamma_1) \nabla u_0 \cdot \nabla N(\cdot, y) \right|.$$

Observe that, since $\gamma_0 \in C^{1,\alpha}(\Omega)$, by interior regularity results ([4, Theorem 2.1, Chapter 2], by [5] and by (2) we get

$$\|\nabla u_0\|_{L^{\infty}(D^1_{\epsilon})} \leq C \|\psi\|_{H^{-1/2}(\partial\Omega)}, \tag{12}$$
$$|\nabla N(x,y)| \leq \frac{C}{|x-y|},$$
d, since $y \in \partial\Omega$
$$\|\nabla N(\cdot,y)\|_{L^{\infty}(D^1_{\epsilon})} \leq C. \tag{13}$$
hce, by (12), (13) and Lemma 3.1.

and, since $y \in \partial \Omega$

Hence, by
$$(12)$$
, (13) and Lemma 3.1,

$$|I_2| \le C \left| D_{\epsilon}^1 \setminus D_{\epsilon}^{1,\theta} \right| \|\psi\|_{H^{-1/2}(\partial\Omega)} \le C \epsilon^{1+\theta} \|\psi\|_{H^{-1/2}(\partial\Omega)}.$$

We now define

$$\Sigma_{\eta}^{\theta} = \left\{ x + \eta n_1(x) : x \in \Sigma_1, \, dist(x, P_1 \cup Q_1) > \epsilon^{\theta} \right\}$$

Due to the regularity of Σ_1 , if we denote by $d\sigma_x^{\eta}$ the arclength measure on Σ_{η}^{θ} and by $d\sigma_x$ the arclength measure on Σ_1 , we have

$$d\sigma_x^\eta = (1 + O(\eta)) d\sigma_x$$

For every point $x + \eta n(x) \in D^{1,\theta}_{\epsilon}$, let $x_{\epsilon} = x + \epsilon n(x)$. By (11),

$$\begin{aligned} |\nabla u_{\epsilon}(x+\eta n(x)) - \nabla u_{\epsilon}(x_{\epsilon})| &\leq C|x+\eta n(x) - x_{\epsilon}|^{\beta} \epsilon^{-\theta(1+\beta)} \|\psi\|_{H^{-1/2}(\partial\Omega)} \\ &\leq C \epsilon^{\beta-\theta(1+\beta)} \|\psi\|_{H^{-1/2}(\partial\Omega)} \end{aligned}$$

and, also,

$$|(\gamma_1 - \gamma_0)(x + \eta n(x)) - (\gamma_1 - \gamma_0)(x_{\epsilon})| \le C\epsilon^{\alpha}$$

so that

$$\int_{D_{\epsilon}^{1,\theta}} (\gamma_0 - \gamma_1) \nabla u_{\epsilon} \nabla_x N = 2\epsilon \int_{\Sigma_{\epsilon}^{\theta}} (\gamma_0 - \gamma_1) \nabla u_{\epsilon}^i \nabla_x N + o(\epsilon),$$

where we set

$$u_{\epsilon}^{i} = u_{\epsilon|_{D_{\epsilon}^{1}}}, \quad u_{\epsilon}^{e} = u_{\epsilon|_{\Omega\setminus\overline{D}_{\epsilon}^{1}}}.$$

We now use the transmission conditions

$$u_{\epsilon}^{i} = u_{\epsilon}^{e},$$
$$\gamma_{1} \frac{\partial u_{\epsilon}^{i}}{\partial n} = \gamma_{0} \frac{\partial u_{\epsilon}^{e}}{\partial n}$$

that are satisfied on $\partial D_{\epsilon}^{1,\theta}$ pointwise, in order to obtain, finally,

$$\int_{D_{\epsilon}^{1,\theta}} (\gamma_0 - \gamma_1) \nabla u_{\epsilon}^i \nabla N$$

= $2\epsilon \int_{\Sigma_{\epsilon}^{\theta}} (\gamma_0 - \gamma_1) \left\{ \frac{\gamma_0}{\gamma_1} \frac{\partial u_{\epsilon}^e}{\partial n} \frac{\partial N}{\partial n_x} + \frac{\partial u_{\epsilon}^e}{\partial \tau} \frac{\partial N}{\partial \tau_x} \right\} + o(\epsilon).$

Assume that

$$\|\nabla u^e_{\epsilon} - \nabla u^e_0\|_{L^{\infty}(\Sigma^{\theta}_{\epsilon})} \le C\epsilon^{\theta_1} \|\psi\|_{H^{-1/2}(\partial\Omega)}$$
(14)

for some $\theta_1 > 0$. Then

$$\int_{D_{\epsilon}^{1,\theta}} (\gamma_0 - \gamma_1)(x) \nabla u_{\epsilon}^i(x) \nabla N(x,y) dx$$

= $2\epsilon \int_{\Sigma_{\epsilon}^{\theta}} (\gamma_0 - \gamma_1) \left\{ \frac{\gamma_0}{\gamma_1} \frac{\partial u_0^e}{\partial n_1} \frac{\partial N}{\partial n_1} + \frac{\partial u_0^e}{\partial \tau_1} \frac{\partial N}{\partial \tau_1} \right\} d\sigma_x^{\epsilon} + o(\epsilon)$
= $2\epsilon \int_{\Sigma_1} (\gamma_0 - \gamma_1) \mathbb{M}^1(x) \nabla u_0(x) \nabla_x N(x,y) d\sigma_x + o(\epsilon),$

216

which concludes the proof.

So, we are left with the proof of (14). Let $2\epsilon < d < \frac{1}{2K}$ and let

$$\Omega_d^{\epsilon} = \left\{ x \in \Omega : dist(x, \partial(\Omega \setminus D_{\epsilon}^1)) > d \right\}.$$

Since $u_{\epsilon} - u_0$ is solution of

$$\operatorname{div}(\gamma_0 \nabla (u_{\epsilon} - u_0)) = 0 \text{ in } \Omega \setminus D_{\epsilon}^1$$

the regularity assumption on γ_0 implies that $u_{\varepsilon} - u_0 \in H^2_{loc}(\Omega \setminus D^1_{\epsilon})$ (see [4, Theorem 2.1, Chapter 2]). Consider $\Phi^k_{\epsilon} = \frac{\partial}{\partial x_k}(u_{\epsilon} - u_0)$ for k = 1, 2. The function Φ^k_{ϵ} satisfies in $\Omega \setminus D^1_{\epsilon}$

$$\operatorname{div}\left(\gamma_0 \nabla \Phi_{\epsilon}^k\right) = -\operatorname{div}\left(\frac{\partial \gamma_0}{\partial x_k} \nabla (u_{\epsilon} - u_0)\right) =: F.$$

By Caccioppoli inequality and by Lemma 8 we have that

$$\begin{split} \|\nabla \Phi_{\epsilon}^{k}\|_{L^{2}(\Omega_{d/2}^{\epsilon})}^{2} &\leq \frac{C}{d^{2}} \|\Phi_{\epsilon}^{k}\|_{L^{2}(\Omega_{d/4}^{\epsilon})}^{2} + \|F\|_{H^{-1}(\Omega_{d/4}^{\epsilon})}^{2} \\ &\leq C\left(\frac{1}{d^{2}}\|\Phi_{\epsilon}^{k}\|_{L^{2}(\Omega_{d/4}^{\epsilon})}^{2} + \|\nabla(u_{\epsilon}-u_{0})\|_{L^{2}(\Omega)}^{2}\right) \\ &\leq C\left(\frac{1}{d^{2}}+1\right)\|\nabla(u_{\epsilon}-u_{0})\|_{L^{2}(\Omega)}^{2} \\ &\leq C\left(\frac{1}{d^{2}}+1\right)\epsilon\|\psi\|_{H^{-1/2}(\partial\Omega)}^{2}. \end{split}$$

Hence

$$\|\Phi^k_{\epsilon}\|_{H^1(\Omega^{\epsilon}_{d/2})} \le C\sqrt{\epsilon}d^{-1}\|\psi\|_{H^{-1/2}(\partial\Omega)}.$$

Applying Lemma 3.3 to Φ_{ϵ}^k gives

$$\|\nabla \Phi_{\epsilon}^{k}\|_{L^{2+\eta}(\Omega_{d}^{\epsilon})} \leq C\left(\|F\|_{H^{-1,2+\eta}(\Omega_{d/2}^{\epsilon})} + d^{\frac{2}{2+\eta}-1}\|\nabla \Phi_{\epsilon}^{k}\|_{L^{2}(\Omega_{d/2}^{\epsilon})}^{2}\right).$$

Now, by

$$\|F\|_{H^{-1,2+\eta}(\Omega_{d/2}^{\epsilon})} \le C \|\nabla(u_{\epsilon} - u_0)\|_{L^{2+\eta}(\Omega_{d/2}^{\epsilon})}$$

and by the interior regularity estimates and Sobolev Immersion Theorem

$$\begin{aligned} \|\nabla(u_{\epsilon} - u_{0})\|_{L^{2+\eta}(\Omega_{d/2}^{\epsilon})} &\leq C \|u_{\epsilon} - u_{0}\|_{H^{2}(\Omega_{d/2}^{\epsilon})} \\ &\leq C \|u_{\epsilon} - u_{0}\|_{H^{1}(\Omega_{d/4}^{\epsilon})} \leq \|u_{\epsilon} - u_{0}\|_{H^{1}(\Omega)} \end{aligned}$$

and hence

$$\begin{aligned} \|\nabla \Phi_{\epsilon}^{k}\|_{L^{2+\eta}(\Omega_{d}^{\epsilon})} &\leq C\left(\|u_{\epsilon}-u_{0}\|_{H^{1}(\Omega)}+d^{\frac{2}{2+\eta}-1}\|\nabla \Phi_{\epsilon}^{k}\|_{L^{2}(\Omega_{d/2}^{\epsilon})}^{2}\right) \\ &\leq C\left(1+d^{\frac{2}{2+\eta}-2}\right)\sqrt{\epsilon}\|\psi\|_{H^{-1/2}(\partial\Omega)}.\end{aligned}$$

Finally, since $\frac{2}{2+\eta} - 2 < 0$ and d < 1, from last inequality, we derive

$$\|\nabla \Phi^k_{\epsilon}\|_{L^{2+\eta}(\Omega^{\epsilon}_d)} \le C d^{\frac{2}{2+\eta}-2} \sqrt{\epsilon} \, \|\psi\|_{H^{-1/2}(\partial\Omega)}.$$

On the other hand, applying Lemma 3.3 to $u_{\epsilon} - u_0$ we have

$$\|\Phi_{\epsilon}^{k}\|_{L^{2+\eta}(\Omega_{d}^{\epsilon})} \leq C d^{\frac{2}{2+\eta}-1} \sqrt{\epsilon} \|\psi\|_{H^{-1/2}(\partial\Omega)}.$$

By Sobolev Imbedding Theorem we than have

$$\left\|\frac{\partial}{\partial x_k}(u_{\epsilon}-u_0)\right\|_{L^{\infty}(\Omega_d^{\epsilon})} \le C d^{\frac{2}{2+\eta}-2} \sqrt{\epsilon} \|\psi\|_{H^{-1/2}(\partial\Omega)}.$$
(15)

Now let $y \in \Sigma'_{\epsilon}$ and y_d be the closest point to y in Ω^{ϵ}_d . By (11) we have

$$|\nabla u_{\epsilon}(y) - \nabla u_{\epsilon}(y_d)| \le C \frac{d^{\beta}}{\epsilon^{\theta(\beta+1)}} \|\psi\|_{H^{-1/2}(\partial\Omega)}.$$
 (16)

Hence, by (15) and (16) we have

$$|\nabla (u_{\epsilon}^{e} - u_{0})(y)| \leq C \left(d^{\beta} \epsilon^{-\theta(\beta+1)} + d^{-2 + \frac{2}{2+\eta}} \sqrt{\epsilon} \right) \|\psi\|_{H^{-1/2}(\partial\Omega)}.$$

Choosing $\theta < \frac{\beta}{2(2-\frac{2}{2+\eta})(\beta+1)}$ we get

$$|\nabla (u_{\epsilon}^e - u_0)(y)| \le C\epsilon^{\theta_1}$$

with $\theta_1 > 0$.
